### Abstract

Since early 2006 the Meteoroid Environment Office (MEO) at NASA's Marshall Space Flight Center has routinely monitored the Moon for impact flashes produced by meteoroids striking the lunar surface. Activity from from the Geminid meteor shower (GEM) was observed in 2015, resulting in the detection of 45 lunar impact flashes (roughly 109 for the NASA dataset), in about 10 hours of observation with peak R magnitudes ranging from 6.5 to 11. A subset of 30 of these flashes, observed 14-15 December, was analyzed in order to determine the luminous efficiency, the ratio of emitted luminous energy to the meteoroid's kinetic energy, using the technique of [1]. The resulting luminous efficiency, found to range between  $\eta = 1.8 \times 10^4$  and  $3.3 \times 10^3$ , depending on the assumed mass index and flux, was then applied to calculate the masses of Geminid meteoroids striking the Moon in 2015.

### Background

$$E_l = \eta E_k$$

ninous efficiency is imperative to calculating the kinetic energy and mass of a meteoroid, as well as r of be determined in the laboratory at meteogoids speeds and sizes due to mechanical constraints.

$$N(E_{l}) = \left(\frac{2 E_{l}}{\eta m_{o} V^{2}}\right)^{1-s} \int_{t_{i}}^{t_{2}} F(m_{o}, t) A(t) dt$$

 $N = \int_{t}^{t_{2}} F(t) A(t) dt$ 

ere F(t) is the flux as a function of time and A is the observed lunar area that is perpendicular to the m o as a function of time.

$$F(m) = F(m_0) \left(\frac{m}{m_0}\right)^{1-\alpha}$$

 $F(m)=F(m_0)\left(\frac{m}{m_0}\right)^{1-s}$  where F(m) is the flux of particles having mass greater than m,  $F(m_0)$  is the flux of particles of kno and s is the mass index.

$$F(E_k) = F(m_0) \left(\frac{2 E_k}{m_0 V^2}\right)^{1-s}$$

Solving  $E_1 = \eta E_k$  for  $E_k$  and substituting this into Eq. (3) gives a cumulative flux distribution as a function of lur

$$F(E_{\parallel}) = F(m_0) \left( \frac{2 E_{\parallel}}{\eta m_0 V^2} \right)^{1-s}$$

$$N(E_{\parallel}) = \left(\frac{2 E_{\parallel}}{\eta m_{o} V^{2}}\right)^{1-s} \int_{t_{1}}^{t_{2}} F(m_{o}, t) A(t) dt$$
 (5)

This result is comparable to Eq (4) of [1] and identical to the treatment in [5].

Date	Timespan (UT)	Tot .Time (hr)	# Impacts	Raw rate (#/hr)
14-15 Dec 2015	23:25-01:41	2.26	32	14.1
15-16 Dec 2015	23:21-02:41	3.33	9	2.7
17-18 Dec 2015	23:44-04:18	4.56	4	0.9

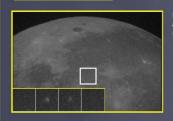

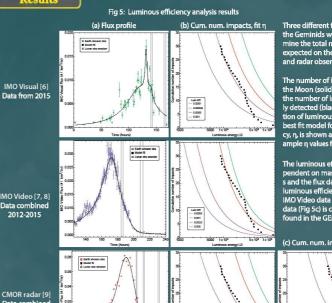

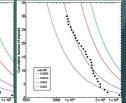

Fig 2: GEM lunar impact flashes observed on 15 Dec 2015 at (top) 00:07:21 UT and (bottom) 01:20:43 UT, with flash frame sequence inset.

The cumulative histogram of flash magnitudes, Fig. 4, shows that a turnover occurs at mg = 9.5 for the whole dataset as well as December 14-15. This fet ture indicates a completeness limit of Ej = 8.3  $\times$  10  $^3$  . Observations recorded 15-16 December and 17-18 December were excluded from this study as a completness limit could not be determined. These selection criteria reduced the dataset from 45 to 30 impact flashes.
